A/B testing

A statistical way of comparing two (or more) techniques, typically an incumbent against a new rival. A/B testing aims to determine not only which technique performs better but also to understand whether the difference is statistically significant. A/B testing usually considers only two techniques using one measurement, but it can be applied to any finite number of techniques and measures.

accuracy

 Based on this (#recommendation

~ 15-16%

The fraction of **predictions** (#prediction) that a **classification model** (#classification_model) got right in **multi-class classification** (#multi-class), accuracy is defined as follows:

$$\text{Accuracy} = \frac{\text{Correct Predictions}}{\text{Total Number Of Examples}}$$

In **binary classification** (#binary_classification), accuracy has the following definition:

$$\text{Accuracy} = \frac{\text{True Positives} + \text{True Negatives}}{\text{Total Number Of Examples}}$$

See **true positive** (#TP) and **true negative** (#TN). Contrast **accuracy** with **precision** (#precision) and **recall** (#recall).

Click the icon for additional notes.

In a **class-imbalanced dataset** (#class_imbalanced_data_set), great accuracy does not always imply a great model. For example, snow falls approximately 24 times per century in a certain subtropical city. So, a binary classification snow forecasting model that automatically predicted "no snow" every day would be about 99.93% accurate. Although 99.93% accuracy seems very high, the model actually has no predictive power.

Accuracy is just one of many metrics for determining how valuable a classification model's predictions are. For example, **precision** (#precision) and **recall** (#recall) are usually more useful metrics than **accuracy** for assessing class-imbalanced datasets.

action

RL

In reinforcement learning, the mechanism by which the **agent** (#agent) transitions between **states** (#state) of the **environment** (#environment). The agent chooses the action by using a **policy** (#policy).

Based on this (#recommendation)

activation function

An **activation function** (for example, **ReLU** (#ReLU) or **sigmoid** (#sigmoid_function)) that takes in the weighted sum of all of the inputs from the previous layer and then generates and passes an output value (typically nonlinear) to the next layer.

Updated Feb 11, 2020

active learning

A **training** (#training) approach in which the algorithm chooses some of the data it learns from. Active learning is particularly valuable when **labeled examples** (#labeled_example) are scarce or expensive to obtain. Instead of blindly seeking a diverse range of labeled examples, an active learning algorithm selectively seeks the particular range of examples it needs for learning.

Updated Aug 18, 2021

AdaGrad

A sophisticated gradient descent algorithm that rescales the gradients of each parameter, effectively giving each parameter an independent **learning rate** (#learning_rate). For a full explanation, see [this paper](http://www.jmlr.org/papers/volume12/duchi11a/duchi11a.pdf) (http://www.jmlr.org/papers/volume12/duchi11a/duchi11a.pdf).

agent

RL

In reinforcement learning, the entity that uses a **policy** (#policy) to maximize expected **return** (#return) gained from transitioning between **states** (#state) of the **environment** (#environment).

Based on this (#recommendation

~ 15-16

agglomerative clustering

See **hierarchical clustering** (#hierarchical_clustering).

Updated Feb 11, 2020

anomaly detection

The process of identifying **outliers** (#outliers). For example, if the mean for a certain **feature** (#feature) is 100 with a standard deviation of 10, then anomaly detection should flag a value of 200 as suspicious.

Updated Aug 18, 2021

Backpropagation

```
j rec=CjdodHRwczovL2RldmVsb3Blc
```

The primary algorithm for performing **gradient descent** (#gradient_descent) on **neural networks**

(#newsL, #newsW, #newsB, #newsC, #newsT) First, the output values of each node are calculated (and cached) in a forward

pass. Then, the Partial Derivative (#partial_derivative) of the error with respect to each parameter is calculated in a backward pass through the graph.

Updated Feb 11, 2020

bag of words

abc

A representation of the words in a phrase or passage, irrespective of order. For example, bag of words represents the following three phrases identically:

- the dog jumps
- jumps the dog
- dog jumps the

Based on this (#recommendation

a link)

Each word is mapped to an index in a **sparse vector** (#sparse_vector), where the vector has an index for every word in the vocabulary. For example, the phrase *the dog jumps* is mapped into a feature vector with non-zero values at the three indices corresponding to the words *the*, *dog*, and *jumps*. The non-zero value can be any of the following:

- A 1 to indicate the presence of a word.
- A count of the number of times a word appears in the bag. For example, if the phrase were *the maroon dog is a dog with maroon fur*, then both *maroon* and *dog* would be represented as 2, while the other words would be represented as 1.

Updated Feb 11, 2020.

See **other values**, such as the logarithm of the count of the number of times a word appears in the bag.

Updated Aug 18, 2021

baseline (#baseline)

A **model** (#model) used as a reference point for comparing how well another model (typically, a more complex one) is performing. For example, a **logistic regression model** (#logistic_regression) might serve as a good baseline for a **deep model** (#deep_model).

For a particular problem, the baseline helps model developers quantify the minimal expected performance that a new model must achieve for the new model to be useful.

batch

The set of examples used in one **iteration** (#iteration) (that is, one **gradient** (#gradient) update) of **model training** (#model_training).

See also **batch size** (#batch_size).

Updated Feb 11, 2020

Bayesian neural network

A probabilistic **neural network** (#neural_network) that accounts for uncertainty in **weights**

(#weight) and outputs. A standard neural network regression model typically **predicts**

(#prediction) a scalar value; for example, a model predicts a house price of 853,000. By

contrast, a Bayesian neural network predicts a distribution of values; for example, a model

predicts a house price of 853,000 with a standard deviation of 67,200. A Bayesian neural

network relies on **Bayes' Theorem**

(https://betterexplained.com/articles/an-intuitive-and-short-explanation-of-bayes-theorem/) to calculate

uncertainties in weights and predictions. A Bayesian neural network can be useful when it is

important to quantify uncertainty, such as in models related to pharmaceuticals. Bayesian

neural networks can also help prevent **overfitting** (#overfitting).

★ Based on this (#recommendation

a B-1A

A model architecture for text **representation** (#representation). A trained BERT model can act as part of a larger model for text classification or other ML tasks.

BERT has the following characteristics:

- Uses the **Transformer** (Transformer) architecture, and therefore relies on **self-attention** (#self-attention).
- Uses the **encoder** (#encoder) part of the Transformer. The encoder's job is to produce good text representations, rather than to perform a specific task like classification.

Updated Feb 16, 2021

Pre (https://developers.google.com/machine-learning/crash-

- Is **bidirectional** (#bidirectional).

)

Updated Feb 11, 2020

broadcasting

Expanding the shape of an operand in a matrix math operation to **dimensions** (#dimensions) compatible for that operation. For instance, linear algebra requires that the two operands in a matrix addition operation must have the same dimensions. Consequently, you can't add a matrix of shape (m, n) to a vector of length n. Broadcasting enables this operation by virtually expanding the vector of length n to a matrix of shape (m,n) by replicating the same values down each column.

For example, given the following definitions, linear algebra prohibits $A+B$ because A and B have different dimensions:

✦ Based on this (#recommendation
A: 1x10
B: 10x10

```
A = [[7, 10, 4],
      [13, 5, 9]]
B = [2]
```

However, broadcasting enables the operation $A+B$ by virtually expanding B to:

```
[[2, 2, 2],
 [2, 2, 2]]
```

Thus, $A+B$ is now a valid operation:

```
[[7, 10, 4], + [[2, 2, 2], = [[ 9, 12, 6],
 [13, 5, 9]]   [2, 2, 2]]   [15, 7, 11]]
```

See the following description of [broadcasting in NumPy](https://developers.google.com/machine-learning/crash-course/scipy/video-deep-learning) (<https://developers.google.com/machine-learning/crash-course/scipy/video-deep-learning>) for more details.

bucketing

Converting a (usually **continuous** (#continuous_feature)) feature into multiple binary features called buckets or bins, typically based on value range. For example, instead of representing temperature as a single continuous floating-point feature, you could chop ranges of temperatures into discrete bins. Given temperature data sensitive to a tenth of a degree, all temperatures between 0.0 and 15.0 degrees could be put into one bin, 15.1 to 30.0 degrees could be a second bin, and 30.1 to 50.0 degrees could be a third bin.

candidate generation

The initial set of recommendations chosen by a recommendation system. For example, consider a bookstore that offers 100,000 titles. The candidate generation phase creates a much smaller list of suitable books for a particular user, say 500. But even 500 books is way too many to recommend to a user. Subsequent, more expensive, phases of a recommendation system (such as **scoring** (#scoring) and **re-ranking** (#re-ranking)) whittle down those 500 to a much smaller, more useful set of recommendations.

Updated Feb 11, 2020

candidate sampling

A training-time optimization in which a probability is calculated for all the positive labels, using, for example, **softmax** (#softmax), but only for a random sample of negative labels. For example, if we have an example labeled *beagle* and *dog* candidate sampling computes the predicted probabilities and corresponding loss terms for the *beagle* and *dog* class outputs in addition to a random subset of the remaining classes (*cat*, *lollipop*, *fence*). The idea is that the **negative classes** (#negative_class) can learn from less frequent negative reinforcement as long as **positive classes** (#positive_class) always get proper positive reinforcement, and this is indeed observed empirically. The motivation for candidate sampling is a computational efficiency win from not computing predictions for all negatives.

ning

category data

Features (#discrete_feature) Drawing a discrete feature named house style, which has a discrete set of three possible values: Tudor , ranch , colonial. By representing house style as categorical data, the model can learn the separate impacts of Tudor , ranch , and colonial on house price.

Some times, values in the discrete set are mutually exclusive, and only one value can be applied to a given example. For example, a car maker categorical feature would probably permit only a single value (Toyota) per example. Other times, more than one value may be applicable. A single car could be painted more than one different color, so a car color categorical feature would permit a single example to have multiple values (for example, red and white).

Data that captures the state of the variables of a model at a particular time. Checkpoints enable exporting model **weights** (#weight), as well as performing training across multiple sessions. Checkpoints also enable training to continue past errors (for example, job preemption). Note that the **graph** (#graph) itself is not included in a checkpoint.

Updated Feb 11, 2020

class

One of a set of enumerated target values for a label. For example, in a **binary classification** (#binary_classification) model that detects spam, the two classes are *spam* and *not spam*. In a **multi-class classification** (#multi-class) model that identifies dog breeds, the classes would be *poodle*, *beagle*, *pug*, and so on.

Based on this (#recommendation)

classification model

A type of machine learning model for distinguishing among two or more discrete classes. For example, a natural language processing classification model could determine whether an input sentence was in French, Spanish, or Italian. Compare with **regression model** (#regression_model)

Updated Feb 11, 2020

classification threshold

A scalar value criterion that is applied to a model's predicted score in order to separate the **positive class** (#positive_class) from the **negative class** (#negative_class). Used when mapping **logistic regression** (#logistic_regression) results to **binary classification** (#binary_classification). For example, consider a logistic regression model that determines the probability of a given email message being spam. If the classification threshold is 0.9, then logistic regression values above 0.9 are classified as *spam* and those below 0.9 are classified as *not spam*.

Updated Aug 18, 2021

class-imbalanced dataset

A **binary classification** (#binary_classification) problem in which the **labels** (#label) for the two classes have significantly different frequencies. For example, a disease dataset in which 0.0001 of examples have positive labels and 0.9999 have negative labels is a class-imbalanced problem, but a football game predictor in which 0.51 of examples label one team winning and 0.49 label the other team winning is *not* a class-imbalanced problem.

clipping

Based on this (#recommendation)

A technique for handling **outliers** (#outliers). Specifically, reducing feature values that are greater than a set maximum value down to that maximum value. Also, increasing feature values that are less than a specific minimum value up to that minimum value.

For example, suppose that only a few feature values fall outside the range 40–60. In this case, you could do the following.

- Clip all values over 60 to be exactly 60.
- Clip all values under 40 to be exactly 40.

In addition to bringing input values within a designated range, clipping can also be used to force gradient descent to use a designated range during training.

Cloud TPU

A specialized hardware accelerator designed to speed up machine learning workloads on Google Cloud Platform.

clustering

Grouping related **examples** (#example), particularly during **unsupervised learning** (#unsupervised_machine_learning). Once all the examples are grouped, a human can optionally supply meaning to each cluster.

Many clustering algorithms exist. For example, the **k-means** (#k-means) algorithm clusters examples based on their proximity to a **centroid** (#centroid), as in the following diagram:

cluster 2

tree width

tree height

A human researcher could then review the clusters and, for example, label cluster 1 as "dwarf trees" and cluster 2 as "full-size trees."

As another example, consider a clustering algorithm based on an example's distance from a center point, illustrated as follows:

machine-learning/crash-course/framing/video-lecture?

rec=CjdodHRwczovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5ILWxIYXJuaW5nL2dsb3NzYXJ5EAIEYDSADKAEwDTolMzkzMDAzMDk)

co-adaptation

When **neurons** (#neuron) predict patterns in training data by relying almost exclusively on outputs of specific other neurons instead of relying on the network's behavior as a whole. When the patterns that cause co-adaption are not present in validation data, then co-adaptation causes overfitting. **Dropout regularization** (#dropout_regularization) reduces co-adaptation because dropout ensures neurons cannot rely solely on specific other neurons.

collaborative filtering

Based on this

(#recommendation

...

Making predictions (#prediction) about the interests of one user based on the interests of many other users. **Collaborative filtering** is often used in **recommendation systems**

Pre (https://developers.google.com/machine-learning/crash-course/ml-intro?rec=CjdodHRwczoVL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwCToIMzkzMdAzMDk)

confirmation bias

The tendency to search for, interpret, favor, and recall information in a way that confirms one's preexisting beliefs or hypotheses. Machine learning developers may inadvertently collect or label data in ways that influence an outcome supporting their existing beliefs. Confirmation bias is a form of **implicit bias** (#implicit_bias).

Experimenter's bias is a form of confirmation bias in which an experimenter continues training models until a preexisting hypothesis is confirmed.

F (https://developers.google.com/machine-learning/crash-course/framing/video-lecture?rec=CjdodHRwczoVL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwCToIMzkzMdAzMDk)

confusion matrix

An $N \times N$ table that summarizes how successful a **classification model's** (#classification_model) predictions were; that is, the correlation between the label and the model's classification. One axis of a confusion matrix is the **label** (#label) that the model predicted, and the other axis is the actual label. N represents the number of **classes** (#class). In a **binary classification** (#binary_classification) problem, $N=2$. For example, here is a sample confusion matrix for a binary classification problem:

	Tumor (predicted)	Non-Tumor (predicted)
Tumor (actual)	18	1
Non-Tumor (actual)	6	452

The preceding confusion matrix shows that of the 19 samples that actually had tumors, the model correctly classified 18 as having tumors (18 **true positives** (#TP)), and incorrectly

Based on this (#recommendation)

classified 1 as not having a tumor (1 **false negative** (#FN)). Similarly, of 458 samples that actually did not have tumors, 452 were correctly classified (452 **true negatives** (#TN)) and 6 were incorrectly classified (6 **false positives** (#FP)).

The confusion matrix for a **multi-class classification** (#multi-class) problem can help you determine mistake patterns. For example, a confusion matrix could reveal that a model trained to recognize handwritten digits tends to mistakenly predict 9 instead of 4, or 1 instead of 7.

Confusion matrices contain sufficient information to calculate a variety of performance metrics, including **precision** (#precision) and **recall** (#recall).

continuous feature

A floating-point feature with an infinite range of possible values. Contrast with **discrete feature** (#discrete_feature).

convenience sampling

Using a dataset not gathered scientifically in order to run quick experiments. Later on, it's essential to switch to a scientifically gathered dataset.

convergence

Informally, often refers to a state reached during **training** (#training) in which training **loss** (#loss) and **validation** (#validation) loss change very little or not at all with each iteration after a certain number of iterations. In other words, a model reaches convergence when additional training on the current data will not improve the model. In **deep learning** (#deep_model), loss values

Based on this (#recommendation)

sometimes stay constant or nearly so for many iterations before finally descending, temporarily producing a false sense of convergence.

See also **early stopping** (#early_stopping).

See also Boyd and Vandenberghe, **Convex Optimization**

(https://web.stanford.edu/~boyd/cvxbook/bv_cvxbook.pdf).

convex function
Pre BlcnMuZ29vZ2xlLnNvbS9tYWN

A function f with which the region above the graph of the function is a **convex set** (#convex_set).

The prototypical convex function is shaped something like the letter **U**. For example, the following are all convex functions:

Updated Aug 18, 2021

F ([https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?](https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?andrec=CjdodHRwczoVL2RldmVsb3)

By contrast, the following function is not convex. Notice how the region above the graph is not a convex set.

rec=CjdodHRwczoVL2RldmVsb3BlcnMuZ29vZ2xlLnNvbS9tYWNNoaW5lYXJ5EAEYDSADKAQwCToIMzkzMDAzMDk)

A **strictly convex function** has exactly one local minimum point, which is also the global minimum point. The classic U-shaped functions are strictly convex functions. However, some convex functions (for example, straight lines) are not U-shaped.

A lot of the common **loss functions** (#loss), including the following, are convex functions:

- **L₂ loss** (#L2_loss)
- **Log Loss** (#Log_Loss)
- **L₁ regularization** (#L1_regularization)
- **L₂ regularization** (#L2_regularization)

Many variations of **gradient descent** (#gradient_descent) are guaranteed to find a point close to the minimum of a strictly convex function. Similarly, many variations of **stochastic gradient descent** (#SGD) have a high probability (though, not a guarantee) of finding a point close to the minimum of a strictly convex function.

➤ **Based on this** (#recommendation)

The **sum** of two convex functions (for example, L_2 loss + L_1 regularization) is a convex function.

Deep models (#deep_model) are never convex functions. Remarkably, algorithms designed for **convex optimization** (#convex_optimization) tend to find reasonably good solutions on deep networks anyway, even though those solutions are not guaranteed to be a global minimum.

Updated Feb 11, 2020

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prereqs)

convex optimization

The process of using mathematical techniques such as **gradient descent** (#gradient_descent) to find the minimum of a **convex function** (#convex_function). A great deal of research in machine learning has focused on formulating various problems as convex optimization problems and in solving those problems more efficiently.

For complete details, see Boyd and Vandenberghe, [Convex Optimization](https://web.stanford.edu/~boyd/cvxbook/bv_cvxbook.pdf) (https://web.stanford.edu/~boyd/cvxbook/bv_cvxbook.pdf).

convex set

A subset of Euclidean space such that a line drawn between any two points in the subset remains completely within the subset. For instance, the following two shapes are convex sets:

By contrast, the following two shapes are not convex sets:

convolution

Based on this (#recommendation)

In mathematics, casually speaking, a mixture of two functions. In machine learning, a convolution mixes the convolutional filter and the input matrix in order to train **weights**

(#weight). machine-learning/crash-course/ml-intro?

The term "convolution" in machine learning is often a shorthand way of referring to either **convolutional operation** (#convolutional_operation) or **convolutional layer** (#convolutional_layer).

Without convolutions, a machine learning algorithm would have to learn a separate weight for every cell in a large **tensor** (#tensor). For example, a machine learning algorithm training on 2K x 2K images would be forced to find 4M separate weights. Thanks to convolutions, a machine

learning algorithm only has to find weights for every cell in the **convolutional filter**

(#convolutional_filter), dramatically reducing the memory needed to train the model. When the convolutional filter is applied, it's simply replicated across cells such that each is multiplied by the filter.

Pre (https://developers.google.com/machine-learning/crash-course/preqs-and-prework)

One of the two actors in a **convolutional operation** (#convolutional_operation). (The other actor is a slice of an input matrix.) A convolutional filter is a matrix having the same **rank** (#rank) as the input matrix, but a smaller shape. For example, given a 28x28 input matrix, the filter could be any 2D matrix smaller than 28x28.

In photographic manipulation, all the cells in a convolutional filter are typically set to a constant pattern of ones and zeroes. In machine learning, convolutional filters are typically seeded with random numbers and then the network **trains** (#training) the ideal values.

convolutional layer

A layer of a **deep neural network** (#deep_model) in which a **convolutional filter** (#convolutional_filter) passes along an input matrix. For example, consider the following 3x3

convolutional filter (#convolutional_filter):

Based on this (#recommendation)

The following animation shows a convolutional layer consisting of 9 convolutional operations involving the 5x5 input matrix. Notice that each convolutional operation works on a different 3x3 slice of the input matrix. The resulting 3x3 matrix (on the right) consists of the results of the 9 convolutional operations:

)

A **semi-supervised learning** (#semi-supervised_learning) approach particularly useful when all of the following conditions are true:

- The ratio of **unlabeled examples** (#unlabeled_example) to **labeled examples** (#labeled_example) in the dataset is high.
- This is a classification problem (**binary** (#binary_classification) or **multi-class** (#multi-class)).
- The dataset contains two different sets of predictive features that are independent of each other and complementary.

Co-training essentially amplifies independent signals into a stronger signal. For instance, consider a **classification model** (#classification_model) that categorizes individual used cars as either *Good* or *Bad*. One set of predictive features might focus on aggregate characteristics such as the year, make, and model of the car; another set of predictive features might focus on the previous owner's driving record and the car's maintenance history.

Based on this (#recommendation

The seminal paper on co-training is Combining Labeled and Unlabeled Data with Co-Training (<https://www.cs.cornell.edu/~jef/papers/cotrain.pdf>) by Blum and Mitchell.

decision tree

A model represented as a sequence of branching statements. For example, the following oversimplified decision tree branches a few times to predict the price of a house (in thousands of USD). According to this decision tree, a house larger than 160 square meters, having more than three bedrooms, and built less than 10 years ago would have a predicted price of 510 thousand USD.

disparate impact

Intro (https://developers.google.com/machine-learning/crash-course/ml-intro?rec=CjdodHRwc2ovL2RldmVsb3BlcnMuZ29vZ2xlLnNvbS9tYWNoZW5lLWx1YXJuaW5nL2dsb3NzYXJ5EAIYDSADKAMwDTolMzkzMDAzMDk) Making decisions about people that impact different population subgroups disproportionately. This usually refers to situations where an algorithmic decision-making process harms or benefits some subgroups more than others. For example, suppose an algorithm that determines a Lilliputian's eligibility for a miniature-home loan is more likely to classify them as "ineligible" if their mailing address contains a certain postal code. If Big-Endian Lilliputians are more likely to have mailing addresses with this postal code than Little-Endian Lilliputians, then this algorithm may result in disparate impact.

Contrast with **disparate treatment** (#disparate_treatment), which focuses on disparities that result when subgroup characteristics are explicit inputs to an algorithmic decision-making process.

Updated Aug 18, 2021

F (https://developers.google.com/machine-learning/crash-course/framing/video-lecture?rec=CjdodHRwc2ovL2RldmVsb3BlcnMuZ29vZ2xlLnNvbS9tYWNoZW5lLWx1YXJuaW5nL2dsb3NzYXJ5EAIYDSADKAMwDTolMzkzMDAzMDk)

disparate treatment

Factor in subjects' **sensitive attributes** (#sensitive_attribute) into an algorithmic decision-making process such that different subgroups of people are treated differently.

For example, consider an algorithm that determines Lilliputians' eligibility for a miniature-home loan based on the data they provide in their loan application. If the algorithm uses a Lilliputian's affiliation as Big-Endian or Little-Endian as an input, it is enacting disparate treatment along that dimension.

Contrast with **disparate impact** (#disparate_impact), which focuses on disparities in the societal impacts of algorithmic decisions on subgroups, irrespective of whether those subgroups are inputs to the model.

ig: Because sensitive attributes are almost always correlated with other features the data may have, explicitly ing sensitive attribute information does not guarantee that subgroups will be treated equally. For example, ing sensitive demographic attributes from a training data set that still includes postal code as a feature may

is disparate treatment of subgroups, but there still might be disparate impact upon these groups because pos might serve as a **proxy** (#proxy_sensitive_attributes) for other demographic information.

[F \(https://developers.google.com/machine-learning/crash-course/framing/video-lecture?andrec=CjdoOHwczovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwCToIMzkzMDAzMDk\)](https://developers.google.com/machine-learning/crash-course/framing/video-lecture?andrec=CjdoOHwczovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwCToIMzkzMDAzMDk)
 Updated Feb 11, 2020

RL

In reinforcement learning, a **policy** (#policy) that either follows a **random policy** (#random_policy) with probability ϵ or follows a **greedy policy** (#greedy_policy) otherwise. For example, if epsilon is 0.9, then the policy follows a random policy 90% of the time and a greedy policy 10% of the time.

Over successive episodes, the algorithm reduces epsilon's value in order to shift from following a random policy to following a greedy policy. By shifting the policy, the agent first randomly explores the environment and then greedily exploits the results of random exploration.

equality of opportunity

A **fairness metric** (#fairness_metric) that checks whether, for a preferred **label** (#label) (one that confers an advantage or benefit to a person) and a given **attribute** (#attribute), a classifier predicts that preferred label equally well for all values of that attribute. In other words, equality

Based on this (#recommendation)

of opportunity measures whether the people who should qualify for an opportunity are equally likely to do so, regardless of their group membership.

For example, suppose Glubbubdrib University admits both Lilliputians and Brobdingnagians to a rigorous mathematics program. Lilliputians' secondary schools offer a robust curriculum of math classes, and the vast majority of students are qualified for the university program. Brobdingnagians' secondary schools don't offer math classes at all, and as a result, far fewer of their students are qualified. Equality of opportunity is satisfied for the preferred label of "admitted" with respect to nationality (Lilliputian or Brobdingnagian) if qualified students are equally likely to be admitted, irrespective of whether they're a Lilliputian or a Brobdingnagian.

For example, let's say 100 Lilliputians and 100 Brobdingnagians apply to Glubbubdrib University, and admissions decisions are made as follows:

Table 1. Lilliputian applicants (90% are qualified)

	Qualified	Unqualified
Admitted	45	3
Rejected	45	7
Total	90	10

Percentage of qualified students admitted: $45/90 = 50\%$
Percentage of unqualified students rejected: $7/10 = 70\%$
Total percentage of Lilliputian students admitted: $(45+3)/100 = 48\%$

Table 2. Brobdingnagian applicants (10% are qualified):

	Qualified	Unqualified
Admitted	5	9
Rejected	5	81
Total	10	90

Percentage of qualified students admitted: $5/10 = 50\%$

Percentage of unqualified students rejected: $81/90 = 90\%$

Total percentage of Brobdingnagian students admitted: $(5+9)/100 = 14\%$

The preceding examples satisfy equality of opportunity for acceptance of qualified students because qualified Lilliputians and Brobdingnagians both have a 50% chance of being admitted.

While equality of opportunity is satisfied, the following two fairness metrics are not satisfied:

demographic parity (#demographic_parity): Lilliputians and Brobdingnagians are admitted to the university at different rates; 48% of Lilliputians students are admitted, but only 14% of Brobdingnagian students are admitted.

equalized odds (#equalized_odds): While qualified Lilliputian and Brobdingnagian students both have the same chance of being admitted, the additional constraint that unqualified Lilliputians and Brobdingnagians both have the same chance of being rejected is not satisfied. Unqualified Lilliputians have a 70% rejection rate, whereas unqualified Brobdingnagians have a 90% rejection rate.

See "Equality of Opportunity in Supervised Learning" (<https://arxiv.org/pdf/1610.02413.pdf>) for a more detailed discussion of equality of opportunity. Also see "Attacking discrimination with smarter machine learning" (<https://research.google.com/bigpicture/attacking-discrimination-in-ml/>) for a visual explanation of the tradeoffs when optimizing for equality of opportunity.

equalized odds

A **fairness metric** (#fairness_metric) that checks if, for any particular label and attribute, a classifier predicts that label equally well for all values of that attribute.

For example, suppose Glubbudbrib University admits both Lilliputians and Brobdingnagians to a rigorous mathematics program. Lilliputians' secondary schools offer a robust curriculum of math classes, and the vast majority of students are qualified for the university program. Brobdingnagians' secondary schools don't offer math classes at all, and as a result, far fewer of their students are qualified. Equalized odds is satisfied provided that no matter whether an applicant is a Lilliputian or a Brobdingnagian, if they are qualified, they are equally as likely to get admitted to the program, and if they are not qualified, they are equally as likely to get

rejected on this (#recommendation

Let's say 100 Lilliputians and 100 Brobdingnagians apply to Glubbubdrib University, and admissions decisions are made as follows:

Table 3. Lilliputian applicants (90% are qualified)

	Qualified	Unqualified
Admitted	45	2
Rejected	45	8
Total	90	10

Percentage of qualified students admitted: $45/90 = 50\%$
Percentage of unqualified students rejected: $8/10 = 80\%$
Total percentage of Lilliputian students admitted: $(45+2)/100 = 47\%$

Table 4. Brobdingnagian applicants (10% are qualified):

	Qualified	Unqualified
Admitted	5	18
Rejected	5	72
Total	10	90

Percentage of qualified students admitted: $5/10 = 50\%$
Percentage of unqualified students rejected: $72/90 = 80\%$
Total percentage of Brobdingnagian students admitted: $(5+18)/100 = 23\%$

Equalized odds is satisfied because qualified Lilliputian and Brobdingnagian students both have a 50% chance of being admitted, and unqualified Lilliputian and Brobdingnagian have an 80% chance of being rejected.

While equalized odds is satisfied here, **demographic parity** (`#demographic_parity`) is *not satisfied*. Lilliputian and Brobdingnagian students are admitted to Glubbubdrib University at different rates; 47% of Lilliputian students are

ed, and 23% of Brobdingnagian students are admitted.

Equalized odds is formally defined in "[Equality of Opportunity in Supervised Learning](#)" (https://arxiv.org/pdf/1610.02413.pdf) as follows: "predictor \hat{Y} satisfies equalized odds with respect to protected attributes A and outcome Y if \hat{Y} and A are independent, conditional on Y ."

Contrast equalized odds with the more relaxed **equality of opportunity** (#equality_of_opportunity) metric.

Estimator

A deprecated TensorFlow API. Use **tf.keras** (#tf.keras) instead of Estimators.

example

One row of a dataset. An example contains one or more **features** (#feature) and possibly a **label** (#label). See also **labeled example** (#labeled_example) and **unlabeled example** (#unlabeled_example).

experience replay

RL

In reinforcement learning, a **DQN** (#deep_q-network) technique used to reduce temporal correlations in training data. The **agent** (#agent) stores state transitions in a **replay buffer** (#replay_buffer), and then samples transitions from the replay buffer to create training data.

hashing

In machine learning, a mechanism for bucketing **categorical data** (#categorical_data), particularly when the number of categories is large, but the number of categories actually appearing in the dataset is comparatively small.

For example, Earth is home to about 60,000 tree species. You could represent each of the 60,000 tree species in 60,000 separate categorical buckets. Alternatively, if only 200 of those tree species actually appear in a dataset, you could use hashing to divide tree species into perhaps 500 buckets.

A single bucket could contain multiple tree species. For example, hashing could place *baobab* and *red maple*—two genetically dissimilar species—into the same bucket. Regardless, hashing is still a good way to map large categorical sets into the desired number of buckets. Hashing

Based on this (#recommendation)

session (#session) turns a categorical feature having a large number of possible values into a much smaller number of values by grouping values in a deterministic way.

Updated Feb 11, 2020

hierarchical clustering

A category of **clustering** (#clustering) algorithms that create a tree of clusters. Hierarchical clustering is well-suited to hierarchical data, such as botanical taxonomies. There are two types of hierarchical clustering algorithms:

- **Agglomerative clustering** first assigns every example to its own cluster, and iteratively merges the closest clusters to create a hierarchical tree.
- **Divisive clustering** first groups all examples into one cluster and then iteratively divides the cluster into a hierarchical tree.

Based on this (#recommendation)

MLA

Contrast with **centroid-based clustering** (#centroid_based_clustering).

Intro (https://developers.google.com/machine-learning/crash-course/ml-intro?rec=CjdodHRwcZovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5ILWxIYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAQwCToIMzkzMDAzMDk)

hinge loss

A family of **loss** (#loss) functions for **classification** (#classification_model) designed to find the **decision boundary** (#decision_boundary) as distant as possible from each training example, thus maximizing the margin for each example between examples and the boundary. **KSVMs** (#KSVMs) use hinge loss (or a related function, such as squared hinge loss). For binary classification, the hinge loss function is defined as follows:

$$\text{loss} = \max(0, 1 - (y * y'))$$

where y is the true label, either -1 or +1, and y' is the raw output of the classifier model:

$$y' = b + w_1x_1 + w_2x_2 + \dots w_nx_n$$

Consequently, a plot of hinge loss vs. $(y * y')$ looks as follows:

(https://developers.google.com/machine-learning/crash-course/training/loss-of-hinge?rec=CjdodHRwcZovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5ILWxIYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAQwCToIMzkzMDAzMDk)

holdout data

Examples (#example) intentionally not used ("held out") during training. The **validation dataset** (#validation_set) and **test dataset** (#test_set) are examples of holdout data. Holdout data helps evaluate your model's ability to generalize to data other than the data it was trained on. The loss on the holdout set provides a better estimate of the loss on an unseen dataset than does the loss on the training set.

hyperparameter

Based on this (Recommendation)

The "knobs" that you tweak during successive runs of training a model. For example, **learning rate** (#learning_rate) is a hyperparameter.

Contrast with **parameter** (#parameter).

Mac rec=CjdodHRwczovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5ILWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwCToIMzgzMDAzMDk)

Updated Feb 11, 2020

hyperplane

A boundary that separates a space into two subspaces. For example, a line is a hyperplane in two dimensions and a plane is a hyperplane in three dimensions. More typically in machine learning, a hyperplane is the boundary separating a high-dimensional space. **Kernel Support Vector Machines** (#KSVMs) use hyperplanes to separate positive classes from negative classes, often in a very high-dimensional space.

i.i.d.

Abbreviation for **independently and identically distributed** (#iid).

image recognition

A process that classifies object(s), pattern(s), or concept(s) in an image. Image recognition is also known as **image classification**.

Based on this information

fairness that can be applied to all ML problems.

While this may seem discouraging, incompatibility of fairness metrics doesn't imply that fairness efforts are fruitless. Instead, it suggests that fairness must be defined contextually for a given ML problem, with the goal of preventing harms specific to its use cases.

See "On the (im)possibility of fairness" (<https://arxiv.org/pdf/1609.07236.pdf>) for a more detailed discussion of this topic.

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?andrec=CjdodHRwcZovL2RldmVsb3

independently and identically distributed (i.i.d)

Data drawn from a distribution that doesn't change, and where each value drawn doesn't depend on values that have been drawn previously. An i.i.d. is the ideal gas

(https://wikipedia.org/wiki/Ideal_gas) of machine learning—a useful mathematical construct but almost never exactly found in the real world. For example, the distribution of visitors to a web page may be i.i.d. over a brief window of time; that is, the distribution doesn't change during that brief window and one person's visit is generally independent of another's visit. However, if you expand that window of time, seasonal differences in the web page's visitors may appear.

Updated Feb 11, 2020

individual fairness

A fairness metric that checks whether similar individuals are classified similarly. For example, Brobdingnagian Academy might want to satisfy individual fairness by ensuring that two students with identical grades and standardized test scores are equally likely to gain admission.

Note that individual fairness relies entirely on how you define "similarity" (in this case, grades and test scores), and you can run the risk of introducing new fairness problems if your similarity metric misses important information (such as the rigor of a student's curriculum).

Based on this (#recommendation

~ 1.5k

See ["Fairness Through Awareness"](https://arxiv.org/pdf/1104.3913.pdf) (https://arxiv.org/pdf/1104.3913.pdf) for a more detailed discussion of individual fairness.

intersection over union (IoU)

The intersection of two sets divided by their union. In machine-learning image-detection tasks, IoU is used to measure the accuracy of the model's predicted **bounding box** (#bounding_box) with respect to the **ground-truth** (#ground_truth) bounding box. In this case, the IoU for the two boxes is the ratio between the overlapping area and the total area, and its value ranges from 0 (no overlap of predicted bounding box and ground-truth bounding box) to 1 (predicted bounding box and ground-truth bounding box have the exact same coordinates).

For example, in the image below:

 Based on this (#recommendation)

The predicted bounding box (the coordinates delimiting where the model predicts the night table in the painting is located) is outlined in purple.

The ground-truth bounding box (the coordinates delimiting where the night table in the painting is actually located) is outlined in green.

Here, the intersection of the bounding boxes for prediction and ground truth (below left) is 1, and the union of the bounding boxes for prediction and ground truth (below right) is 7, so the IoU is $\frac{1}{7}$.

item matrix

Updated Feb 11, 2020

In **recommendation systems** (#recommendation_system), a matrix of **embeddings** (#embeddings) generated by **matrix factorization** (#matrix_factorization) that holds latent signals about each **item** (#items). Each row of the item matrix holds the value of a single latent feature for all items. For example, consider a movie recommendation system. Each column in the item matrix represents a single movie. The latent signals might represent genres, or might be harder-to-interpret signals that involve complex interactions among genre, stars, movie age, or other factors.

The item matrix has the same number of columns as the target matrix that is being factorized. For example, given a movie recommendation system that evaluates 10,000 movie titles, the item matrix will have 10,000 columns.

Based on this (#recommendation_system)

items

In a **recommendation system** (#recommendation_system), the entities that a system recommends. For example, videos are the items that a video store recommends, while books are the items that a bookstore recommends.

)

Updated Feb 11, 2020

$$y' = 7 + (-2.5)(x_1) + (-1.2)(x_2) + (1.4)(x_3)$$

Suppose a particular example contains the following values:

- $x_1 = 4$
- $x_2 = -10$
- $x_3 = 5$

Plugging those values into the formula yields a prediction for this example:

$$y' = 7 + (-2.5)(4) + (-1.2)(-10) + (1.4)(5)$$

$$y' = 16$$

Based on this (#recommendation

a B-1A

Linear models tend to be easier to analyze and train than deep models. However, deep models can model complex relationships between features.

<https://developers.google.com/machine-learning/crash-course/prereqs-and-prework/>

Linear regression (#linear_regression) and **logistic regression** (#logistic_regression) are two types of linear models. Linear models include not only models that use the linear equation but also a broader set of models that use the linear equation as part of the formula. For example, logistic regression post-processes the raw prediction (y') to calculate the prediction.

zkzMDAzMDk)

Updated Feb 11, 2020

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prework/

linear regression

Using the raw output (y') of a **linear model** (#linear_model) as the actual prediction in a **regression model** (#regression_model). The goal of a regression problem is to make a real-valued prediction. For example, if the raw output (y') of a linear model is 8.37, then the prediction is 8.37.

<https://developers.google.com/machine-learning/crash-course/training-video-lecture/>

Contrast linear regression with **logistic regression** (#logistic_regression). Also, contrast regression with **classification** (#classification_model).

nnMuZ29vZ2xlLmNvbS9tYWNoaW5lILWxIYXJuaW5nL2dsb3NzYXJ5EA
MYDSADKAEwDTolMzkzMDAzMDk)

Updated Feb 11, 2020

logistic regression

A **classification model** (#classification_model) that uses a **sigmoid function** (#sigmoid_function) to convert a **linear model's** (#linear_model) raw prediction (y') into a value between 0 and 1. You can interpret the value between 0 and 1 in either of the following two ways:

- As a probability that the example belongs to the **positive class** (#positive_class) in a binary classification problem.
- As a value to be compared against a **classification threshold** (#classification_threshold). If the value is equal to or above the classification threshold, the system classifies the example as the positive class. Conversely, if the value is below the given threshold, the system classifies the example as the **negative class** (#negative_class). For example,

➤ **Baseline** (#baseline) the classification threshold is 0.82:

session. Imagine an example that produces a raw prediction (y') of 2.6. The sigmoid of 2.6 is 0.93. Since 0.93 is greater than 0.82, the system classifies this example as the **positive class**.

Imagine a different example that produces a raw prediction of 1.3. The sigmoid of 1.3 is 0.79. Since 0.79 is less than 0.82, the system classifies that example as the **negative class**.

Although logistic regression is often used in **binary classification** (#binary_classification) problems, logistic regression can also be used in **multi-class classification** (#multi-class) problems (where it becomes called **multi-class logistic regression** or **multinomial regression**).

logits

The vector of raw (non-normalized) predictions that a classification model generates, which is ordinarily then passed to a normalization function. If the model is solving a **multi-class classification** (#multi-class) problem, logits typically become an input to the **softmax** (#softmax) function. The softmax function then generates a vector of (normalized) probabilities with one value for each possible class.

In addition, logits sometimes refer to the element-wise inverse of the **sigmoid function** (#sigmoid_function). For more information, see **tf.nn.sigmoid_cross_entropy_with_logits** (https://www.tensorflow.org/api_docs/python/tf/nn/softmax_cross_entropy_with_logits).

Log Loss

The **loss** (#loss) function used in binary **logistic regression** (#logistic_regression).

Based on this (#recommendation)

session

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?rec=CjdodHRwczoVL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAMwDTolMzkzMDAzMDk)

$$\text{odds} = \frac{p}{(1-p)} = \frac{.9}{.1} = 9$$

The **log-odds** is simply the logarithm of the odds. By convention, "logarithm" refers to natural logarithm, but logarithm could actually be any base greater than 1. Sticking to convention, the log-odds of our example is therefore:

MDAzMDk)

$$\text{log-odds} = \ln(9) = 2.2$$

Updated Aug 18, 2021

The **log-odds** are the inverse of the **sigmoid function** (#sigmoid_function).

machine-learning/crash-course/framing/video-lecture?rec=CjdodHRwczoVL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAEwDTolMzkzMDAzMDk

Long Short-Term Memory (LSTM)

▲→□→○

A type of cell in a **recurrent neural network** (#recurrent_neural_network) used to process sequences of data in applications such as handwriting recognition, machine translation, and image captioning. LSTMs address the **vanishing gradient problem** (#vanishing_gradient_problem) that occurs when training RNNs due to long data sequences by maintaining history in an internal memory state based on new input and context from previous cells in the RNN.

loss

Based on this (#recommendation

~ 1.5k

A measure of how far a model's **predictions** (#prediction) are from its **label** (#label). Or, to phrase it more pessimistically, a measure of how bad the model is. To determine this value, a model must define a **loss function**. For example, linear regression models typically use **mean squared error** (#MSE) for a loss function, while logistic regression models use **Log Loss** (#Log_Loss).

rec=CjdodHRwczovL2RldmVsb3BicnMuZ29vZ2xILmNvbS9tYWNoaW5ILWxIYXJuaW5nL2dsb3NzYXJ5EAeyDSADKAQwCToIMzkzMdAzMDk)

A program or system that builds (trains) a predictive model from input data. The system uses the learned model to make useful predictions from new (never-before-seen) data drawn from the same distribution as the one used to train the model. Machine learning also refers to the field of study concerned with these programs or systems.

Pre ([https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?](https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?rec=CjdodHRwc2ovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAMwDTolMzkzMDAzMDk)

majority class

Updated Aug 18, 2021

i rec=CjdodHRwc2ovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAEwDTolMzkzMDAzMDk)

Updated Feb 11, 2020

Markov decision process (MDP)

RL

A graph representing the decision-making model where decisions (or **actions** (#action)) are taken to navigate a sequence of **states** (#state) under the assumption that the **Markov property** (#Markov_property) holds. In reinforcement learning, these transitions between states return a numerical **reward** (#reward).

Markov property

RL

Based on this (#recommendation)

In **recommendation systems** (`#recommendation_system`), the target matrix often holds users' ratings on items (items). For example, the target matrix for a movie recommendation system might look something like the following, where the positive integers are user ratings and 0 means that the user didn't rate the movie:

	Casablanca	The Philadelphia Story	Black Panther	Wonder Woman	Pulp Fiction
User 1	5.0	3.0	0.0	2.0	0.0
User 2	4.0	0.0	0.0	1.0	5.0
User 3	3.0	1.0	4.0	5.0	0.0

The movie recommendation system aims to predict user ratings for unrated movies. For example, will User 1 like *Black Panther*? One approach for recommendation systems is to use matrix factorization to generate the following two matrices:

- A **user matrix** (`#user_matrix`), shaped as the number of users X the number of embedding dimensions
- An **item matrix** (`#item_matrix`), shaped as the number of embedding dimensions X the number of items

For example, using matrix factorization on our three users and five items could yield the following user matrix and item matrix:

User Matrix		Item Matrix				
1.1	2.3	0.9	0.2	1.4	2.0	1.2
0.6	2.0	1.7	1.2	1.2	-0.1	2.1
2.5	0.5					

The dot product of the user matrix and item matrix yields a recommendation matrix that contains not only the original user ratings but also predictions for the movies that each user hasn't seen. For example, consider User 1's rating of *Casablanca*, which was 5.0. The dot product corresponding to that cell in the recommendation matrix should hopefully be around 5.0, and it is:

➤ **Based on this** (`#recommendation`)

$$(1.1 * 0.9) + (2.3 * 1.7) = 4.9$$

More important, will User 1 like Black Panther?

Taking the dot product corresponding to the first row and the third column yields a predicted rating of 4.3:

$$(1.1 * 1.4) + (2.3 * 1.2) = 4.3$$

Matrix factorization typically yields a user matrix and item matrix that, together, are significantly more compact than the target matrix.

$$\text{MAE} = \frac{1}{n} \sum_{i=0}^n |y_i - \hat{y}_i|$$

Mean Squared Error (MSE)

The average squared loss per example. MSE is calculated by dividing the **squared loss**

(#squared_loss) by the number of **examples** (#example). The values that **TensorFlow Playground**

(#TensorFlow_Playground) displays for "Training loss" and "Test loss" are MSE.

Based on this (#recommendation)

Based on this

metric
 A number that you care about. May or may not be directly optimized in a machine-learning system. A metric that your system tries to optimize is called an **objective** (#objective).
 Updated Feb 11, 2020

meta-learning
 A subset of machine learning that discovers or improves a learning algorithm. A meta-learning system can also aim to train a model to quickly learn a new task from a small amount of data from previous tasks and in previous tasks. Meta-learning algorithms generally try to achieve the following:
 • Improve/learn hand-engineered features (such as an initializer or an optimizer).
 • Be more data-efficient and compute-efficient.
 • Improve generalization.
 Meta-learning is related to **few-shot learning** (#few-shot_learning).
 Updated Feb 11, 2020

Metrics API (tf.metrics)

A TensorFlow API for evaluating models. For example, `tf.metrics.accuracy` determines how often a model's predictions match labels.

mini-batch

Based on this (#recommendation)

A **mini-batch** is a randomly selected subset of the entire batch of **examples** (#example) run together in a single iteration of training or inference. The **batch size** (#batch_size) of a mini-batch is usually between 10 and 1000. It is much more efficient to calculate the loss on a mini-batch than on the full training data.

In binary classification (#binary_classification), one class is termed positive and the other is termed negative. The positive class is the thing we're looking for and the negative class is the other possibility. For example, the negative class in a medical test might be "not tumor." The negative class in an email classifier might be "not spam." See also positive class (#positive_class).

neural network

A model that, taking inspiration from the brain, is composed of layers (at least one of which is hidden (#hidden_layer)) consisting of simple connected units or neurons (#neuron) followed by nonlinearities.

Based on this (#recommendation

rec=CjdodHRwczovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5ILWxlYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwDTToIMzkzMDAzMDk)

session
neuron

A **neuron** in a **neural network** (#neural_network), typically taking in multiple input values and generating one output value. The neuron calculates the output value by applying an **activation function** (#activation_function) (a nonlinear transformation) to a weighted sum of input values.

N-gram

An ordered sequence of N words. For example, *truly madly* is a 2-gram. Because order is relevant, *madly truly* is a different 2-gram than *truly madly*.

N Name(s) for this kind of N-gram	Examples
2 bigram or 2-gram	<i>to go, go to, eat lunch, eat dinner</i>
3 trigram or 3-gram	<i>ate too much, three blind mice, the bell tolls</i>
4 4-gram	<i>walk in the park, dust in the wind, the boy ate lentils</i>

Many **natural language understanding** (#natural_language_understanding) models rely on N-grams to predict the next word that the user will type or say. For example, suppose a user typed *three blind*. An NLU model based on trigrams would likely predict that the user will next type *mice*.

Contrast N-grams with **bag of words** (#bag_of_words), which are unordered sets of words.

NLU

Abbreviation for **natural language understanding** (#natural_language_understanding).

- Humans and instruments mis-record or omit feature values.

)

Updated Feb 11, 2020

non-response bias

See **selection bias** (#selection_bias).

nonstationarity

➤ Based on this (#recommendation

a B-1A

session (#session) A feature whose values change across one or more dimensions, usually time. For example, the number of smartphones sold at a particular store demonstrates nonstationarity because that number varies with the season. As a second example, the quantity of a particular fruit harvested in a particular region typically shows sharp nonstationarity over time.

Updated Feb 11, 2020

normalization

The process of converting an actual range of values into a standard range of values, typically -1 to +1 or 0 to 1. For example, suppose the natural range of a certain feature is 800 to 6,000. Through subtraction and division, you can normalize those values into the range -1 to +1.

See also **scaling** (#scaling).

Updated Aug 18, 2021

novelty detection

The process of determining whether a new (novel) example comes from the same distribution as the **training set** (#training_set). In other words, after training on the training set, novelty detection determines whether a *new* example (during inference or during additional training) is an **outlier** (#outliers).

Contrast with **outlier detection** (#outlier-detection).

numerical data

Features (#feature) represented as integers or real-valued numbers. For example, in a real estate model, you would probably represent the size of a house (in square feet or square meters) as numerical data. Representing a feature as numerical data indicates that the

Based on this (#recommendation)

features' values have a *mathematical* relationship to each other and possibly to the label. For example, representing the size of a house as numerical data indicates that a 200 square-meter house is twice as large as a 100 square-meter house. Furthermore, the number of square meters in a house probably has some mathematical relationship to the price of the house.

Not all integer data should be represented as numerical data. For example, postal codes in some parts of the world are integers; however, integer postal codes should not be represented as numerical data in models. That's because a postal code of 20000 is not twice (or half) as

potent as a postal code of 10000. Furthermore, although different postal codes *do* correlate to different real estate values, we can't assume that real estate values at postal code 20000 are

twice as valuable as real estate values at postal code 10000. Postal codes should be

represented as **categorical data** (#categorical_data) instead.

Numerical features are sometimes called **continuous features** (#continuous_feature).

out-group homogeneity bias

The tendency to see out-group members as more alike than in-group members when comparing attitudes, values, personality traits, and other characteristics. **In-group** refers to people you interact with regularly; **out-group** refers to people you do not interact with regularly. If you create a dataset by asking people to provide attributes about out-groups, those attributes may be less nuanced and more stereotyped than attributes that participants list for people in their in-group.

For example, Lilliputians might describe the houses of other Lilliputians in great detail, citing small differences in architectural styles, windows, doors, and sizes. However, the same Lilliputians might simply declare that Brobdingnagians all live in identical houses.

Out-group homogeneity bias is a form of **group attribution bias** (`#group_attribution_bias`).

See also **in-group bias** (`#in-group_bias`).

The algorithm by which variables are divided across **parameter servers** (#Parameter_Server).

perceptron

F (https://developers.google.com/machine-learning/crash-course/framing/video-lecture?rec=CjdodHRwcZovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lWxIYXJuaW5nL2dsb3NzYXJ5EAEwDTToIMzkzMDAzMDk)

A system (either hardware or software) that takes in one or more input values, runs a function on the weighted sum of the inputs, and computes a single output value. In machine learning, the function is typically nonlinear such as **ReLU** (#ReLU), **sigmoid** (#sigmoid_function), or tanh. For example, the following perceptron relies on the sigmoid function to process three input values:

$$f(x_1, x_2, x_3) = \text{sigmoid}(w_1 x_1 + w_2 x_2 + w_3 x_3)$$

In the following illustration, the perceptron takes three inputs, each of which is itself modified by a weight before entering the perceptron:

Perceptrons are the (**nodes** (#node)) in **deep neural networks** (#deep_model). That is, a deep neural network consists of multiple connected perceptrons, plus a **backpropagation** (#backpropagation) algorithm to introduce feedback.

performance

Based on this (#recommendation)

Overloaded term with the following meanings:

- The traditional meaning within software engineering. Namely: How fast (or efficiently) does this piece of software run?
- The meaning within machine learning. Here, performance answers the following question: How good is this **model** (#model)? That is, how good are the model's predictions?

Updated Feb 11, 2020

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?

perplexity

One measure of how well a **model** (#model) is accomplishing its task. For example, suppose your task is to read the first few letters of a word a user is typing on a smartphone keyboard, and to offer a list of possible completion words. Perplexity, P , for this task is approximately the number of guesses you need to offer in order for your list to contain the actual word the user is trying to type.

Updated Aug 18, 2021

Perplexity is related to **cross-entropy** (#cross-entropy) as follows:

$$P = 2^{-\text{cross entropy}}$$

pipeline

The infrastructure surrounding a machine learning algorithm. A pipeline includes gathering the data, putting the data into training data files, training one or more models, and exporting the models to production.

pipelining

(#recommendation

abc

A form of **model parallelism** (#model-parallelism) in which a model's processing is divided into **consecutive stages** and each stage is executed on a different device. While a stage is processing one batch, the preceding stage can work on the next batch.

quantile bucketing

Distributing a feature's values into **buckets** (#bucketing) so that each bucket contains the same (or almost the same) number of examples. For example, the following figure divides 44 points into 4 buckets, each of which contains 11 points. In order for each bucket in the figure to contain the same number of points, some buckets span a different width of x-values.

Based on this (#recommendation)

recommendation system

Updated Feb 11, 2020

A **system** that selects for each user a relatively small set of desirable **items** (#items) from a large corpus. For example, a video recommendation system might recommend two videos from a corpus of 100,000 videos, selecting *Casablanca* and *The Philadelphia Story* for one user, and *Wonder Woman* and *Black Panther* for another. A video recommendation system might base its recommendations on factors such as:

- Movies that similar users have rated or watched.

Updated Aug 18, 2021

- Genre, directors, actors, target demographic...

F (https://developers.google.com/machine-learning/crash-course/framing/video-lecture?rec=CjdodHRwczovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5ILWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwCToIMzkzMDk)

Rectified Linear Unit (ReLU)

An **activation function** (#activation_function) with the following rules:

- If input is negative or zero, output is 0.
- If input is positive, output is equal to input.

recurrent neural network

A **neural network** (#neural_network) that is intentionally run multiple times, where parts of each run feed into the next run. Specifically, hidden layers from the previous run provide part of the input to the same hidden layer in the next run. Recurrent neural networks are particularly useful

Based on this (#recommendation)

for evaluating sequences, so that the hidden layers can learn from previous runs of the neural network on sequential parts of the sequence.

For example, the following figure shows a recurrent neural network that runs four times. Notice that the values learned in the hidden layers from the first run become part of the input to the same hidden layers in the second run. Similarly, the values learned in the hidden layer on the second run become part of the input to the same hidden layer in the third run. In this way, the recurrent neural network gradually trains and predicts the meaning of the entire sequence rather than just the meaning of individual words.

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?rec=CjdodHRwczovL2RldmVsb3BldnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAMwDTolMzkzMDAzMDk)

A type of model that outputs continuous (typically, floating-point) values. Compare with **classification models** (#classification_model), which output discrete values, such as "day lily" or "tiger lily".

Updated Aug 18, 2021
F (https://developers.google.com/machine-learning/crash-course/framing/video-lecture?rec=CjdodHRwczovL2RldmVsb3BldnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAEwDTolMzkzMDAzMDk)

regularization

The penalty on a model's complexity. Regularization helps prevent **overfitting** (#overfitting). Different kinds of regularization include:

- **L₁ regularization** (#L1_regularization)
- **L₂ regularization** (#L2_regularization)
- **dropout regularization** (#dropout_regularization)
- **early stopping** (#early_stopping) (this is not a formal regularization method, but can effectively limit overfitting)

Based on this (#recommendation)

regularization rate

A scalar value, represented as λ , specifying the relative importance of the regularization function. The following simplified **loss** (#loss) equation shows the regularization rate's influence on the loss function:

$$\text{minimize}(\text{loss function} + \lambda(\text{regularization function}))$$

Raising the regularization rate reduces **overfitting** (#overfitting) but may make the model less

accurate (#accuracy)

reinforcement learning (RL)

RL

Updated Aug 18, 2021

A family of algorithms that learn an optimal **policy** (#policy), whose goal is to maximize **return** (#return) when interacting with an **environment** (#environment). For example, the ultimate reward of a reinforcement learning system is to win a game. Reinforcement learning systems can become expert at playing complex games by evaluating sequences of previous game moves that ultimately led to wins and sequences that ultimately led to losses.

replay buffer

RL

In **DQN** (#deep_q-network)-like algorithms, the memory used by the agent to store state transitions for use in **experience replay** (#experience_replay).

reporting bias

Based on this (#recommendation)

session (S-ih-n) The fact that the frequency with which people write about actions, outcomes, or properties is not a reflection of their real-world frequencies or the degree to which a property is characteristic of a class of individuals. Reporting bias can influence the composition of data that machine learning systems learn from.

For example, in books, the word *laughed* is more prevalent than *breathed*. A machine learning model that estimates the relative frequency of laughing and breathing from a book corpus would probably determine that laughing is more common than breathing.

Updated Feb 11, 2020

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?rec=CjdodHRwczovL2RldmVsb3Blc

representation (r-eh-p-ri-zen-tay-shun) The process of mapping data to useful **features** (#feature).

Updated Aug 18, 2021

F (https://developers.google.com/machine-learning/crash-course/framing/video-lecture?rec=CjdodHRwczovL2RldmVsb3Blc

re-ranking (ri-eh-ning) The final stage of a **recommendation system** (#recommendation_system), during which

scored items may be re-graded according to some other (typically, non-ML) algorithm. Re-ranking evaluates the list of items generated by the **scoring** (#scoring) phase, taking actions such as:

- Eliminating items that the user has already purchased.
- Boosting the score of fresher items.

return

RL

In reinforcement learning, given a certain policy and a certain state, the return is the sum of all **rewards** (#reward) that the **agent** (#agent) expects to receive when following the **policy** (#policy)

from the **state** (#state) to the end of the **episode** (#episode). The agent accounts for the delayed nature of expected rewards by discounting rewards according to the state transitions required to obtain the reward.

Therefore, if the discount factor is γ , and r_0, \dots, r_N denote the rewards until the end of the episode, then the return calculation is as follows:

$$\text{Return} = r_0 + \gamma r_1 + \gamma^2 r_2 + \dots + \gamma^{N-1} r_{N-1}$$

Updated Feb 11, 2020

self-attention (also called self-attention layer)

Based on this (#recommendation

a B-1A

A neural network layer that transforms a sequence of **embeddings** (#embeddings) (for instance, **tokens** (#tokens) embeddings) into another sequence of embeddings. Each embedding in the output sequence is constructed by integrating information from the elements of the input sequence through an **attention** (#attention) mechanism.

The self part of self-attention refers to the sequence attending to itself rather than to some other context. Self-attention is one of the main building blocks for **Transformers** (#Transformer) and uses dictionary lookup terminology, such as “query”, “key”, and “value”.

Updated Feb 11, 2020

A self-attention layer starts with a sequence of input representations, one for each word. The input representation for a word can be a simple embedding. For each word in an input sequence, the network scores the relevance of the word to every element in the whole sequence of words. The relevance scores determine how much the word's final representation incorporates the representations of other words.

For example, consider the following sentence:
The animal didn't cross the street because it was too tired.

The animal didn't cross the street because it was too tired.

The following illustration (from [Transformer: A Novel Neural Network Architecture for Language Understanding](https://ai.googleblog.com/2017/08/transformer-novel-neural-network.html)) shows a self-attention layer's attention pattern for the pronoun **it**, with the darkness of each line indicating how much each word contributes to the representation:

The self-attention layer highlights words that are relevant to “it”. In this case, the attention layer has learned to highlight words that **it** might refer to, assigning the highest weight to **animal**.

For a sequence of n **tokens** (#token), self-attention transforms a sequence of embeddings n separate times, once at each position in the sequence.

Refer also to **attention** (#attention) and **multi-head self-attention** (#multi-head-self-attention).

self-supervised learning

Based on this (#recommendation)

A family of techniques for converting an **unsupervised machine learning**

(#unsupervised_machine_learning) problem into a **supervised machine learning**

Self-training works by iterating over the following two steps until the model stops improving:

Updated Feb 11, 2020

1. Use **supervised machine learning** (#supervised_machine_learning) to train a model on the labeled examples.

2. Use the model created in Step 1 to generate predictions (labels) on the unlabeled examples, moving those in which there is high confidence into the labeled examples with the predicted label.

Notice that each iteration of Step 2 adds more labeled examples for Step 1 to train on.

semi-supervised learning

➤ Based on this (#recommendation

~ 15-16

session

S-IIIKK)

Training a model on data where some of the training examples have labels but others don't.

One technique for semi-supervised learning is to infer labels for the unlabeled examples, and then to train on the inferred labels to create a new model. Semi-supervised learning can be useful if labels are expensive to obtain but unlabeled examples are plentiful.

Self-training (#self-training) is one technique for semi-supervised learning.

shape (Tensor)

The number of elements in each **dimension** (#dimensions) of a tensor. The shape is represented as a list of integers. For example, the following two-dimensional tensor has a shape of [3,4]:

```
[[5, 7, 6, 4],
 [2, 9, 4, 8],
 [3, 6, 5, 1]]
```

TensorFlow uses row-major (C-style) format to represent the order of dimensions, which is why the shape in TensorFlow is [3,4] rather than [4,3]. In other words, in a two-dimensional

TensorFlow Tensor, the shape is `[number of rows, number of columns]`.

Intro (https://developers.google.com/machine-learning/crash-course/ml-intro?rec=CjdodHRwcZovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxIYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAEwDTolMzkzMDAzMDk)

sigmoid function

A function that maps logistic or multinomial regression output (log odds) to probabilities, returning a value between 0 and 1. The sigmoid function has the following formula:

$$y = \frac{1}{1 + e^{-\sigma}}$$

where σ is **logistic regression** (`#logistic_regression`) problems is simply:

$$\sigma = b + w_1x_1 + w_2x_2 + \dots w_nx_n$$

Updated Aug 18, 2021

In other words, the sigmoid function converts σ into a probability between 0 and 1.

In some **neural networks** (`#neural_network`), the sigmoid function acts as the **activation function** (`#activation_function`).

sparse feature

Intro (https://developers.google.com/machine-learning/crash-course/ml-intro?rec=CjdodHRwczovL2RldmVsb3BlnMuZ29vZ2xlLnNvbS9tYWNoeSILWxiYXJuaW5nL2dsb3NzYXJ5EAEYDSADKAQwCToIMzkzMPAzmDk)

Feature (#feature) vector whose values are predominately zero or empty. For example, a vector containing a single 1 value and a million 0 values is sparse. As another example, words in a search query could also be sparse feature—there are many possible words in a given language, but only a few of them occur in a given query.

Contrast with **dense feature** (#dense_feature).

Updated Feb 11, 2020

Pre (https://developers.google.com/machine-learning/crash-course/prereqs-and-prework?rec=CjdodHRwczovL2RldmVsb3BlnMuZ29vZ2xlLnNvbS9tYWNoeSILWxiYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAMwDTolMzkz)

sparse representation

A **representation** (#representation) of a tensor that only stores nonzero elements.

Updated Aug 18, 2021

For example, the English language consists of about a million words. Consider two ways to represent a count of the words used in one English sentence:

- A **dense representation** of this sentence must set an integer for all one million cells, and a low integer into a few of them.
- A **sparse representation** of this sentence stores only those cells symbolizing a word actually in the sentence. So, if the sentence contained only 20 unique words, then the sparse representation for the sentence would store an integer in only 20 cells.

For example, consider two ways to represent the sentence, "Dogs wag tails." As the following tables show, the dense representation consumes about a million cells; the sparse representation consumes only 3 cells:

Dense Representation		
Cell Number	Word	Occurrence
0	a	0
1	aardvark	0
2	aargh	0

Based on this

(#recommendation)

Cell Number	Word	Occurrence
3	aarti	0

squared hinge loss

The square of the **hinge loss** (#hinge-loss). Squared hinge loss penalizes outliers more harshly than regular hinge loss.

Updated Feb 11, 2020

squared loss

The **loss** (#loss) function used in **linear regression** (#linear_regression). (Also known as **L₂ Loss**.)

This function calculates the squares of the difference between a model's predicted value for a labeled **example** (#example) and the actual value of the **label** (#label). Due to squaring, this loss function amplifies the influence of bad predictions. That is, squared loss reacts more strongly to outliers than **L₁ loss** (#L1_loss).

TensorFlow

A large-scale, distributed, machine learning platform. The term also refers to the base API layer in the TensorFlow stack, which supports general computation on dataflow graphs.

Although TensorFlow is primarily used for machine learning, you may also use TensorFlow for non-ML tasks that require numerical computation using dataflow graphs.

 Based on this

(#recommendation)

The number of elements a **Tensor** (#tensor) contains in various dimensions. For example, a [5, 10] Tensor has a shape of 5 in one dimension and 10 in another.

Updated Feb 11, 2020

Tensor size

The total number of scalars a **Tensor** (#tensor) contains. For example, a [5, 10] Tensor has a size of 50.

Updated Feb 11, 2020

termination condition

In reinforcement learning, the conditions that determine when an **episode** (#episode) ends, such as when the video reaches a certain state or exceeds a threshold number of state transitions. For example, in tic-tac-toe (https://wikipedia.org/wiki/Tic-tac-toe) (also known as noughts and crosses), an episode terminates either when a player marks three consecutive spaces or when all spaces are marked.

Updated Feb 11, 2020

test set

The subset of the dataset that you use to test your **model** (#model) after the model has gone through initial vetting by the validation set.

Contrast with **training set** (#training_set) and **validation set** (#validation_set).

timestep

One "unrolled" cell within a **recurrent neural network** (#recurrent_neural_network). For example, the following figure shows three timesteps (labeled with the subscripts $t-1$, t , and $t+1$):

token on this (#recommendation)

In a **language model** (`#language-model`), the atomic unit that the model is training on and making predictions on. A token is typically one of the following:

- a word, for example, the phrase "dogs like cats" consists of three word tokens: "dogs", "like", and "cats".
- a character, for example, the phrase "bike fish" consists of nine character tokens. (Note that the blank space counts as one of the tokens.)
- subwords, in which a single word can be a single token or multiple tokens. A subword consists of a root word, a prefix, or a suffix. For example, a language model that uses subwords as tokens might view the word "dogs" as two tokens (the root word "dog" and the plural suffix "s"). That same language model might view the single word "taller" as two subwords (the root word "tall" and the suffix "er").

In domains outside of language models, tokens can represent other kinds of atomic units. For example, in computer vision, a token might be a subset of an image.

Transformer

Intro (https://developers.google.com/machine-learning/crash-course/ml-intro?rec=CjdodHRwc2ovL2RldmVsb3BlcnMuZ29vZ2xILmNvbS9tYWNoaW5lLWxlYXJuaW5nL2dsb3NzYXJ5EAIYDSADKAQwCToIMzkzMdAzMDk)

A **neural network** (#neural_network) architecture developed at Google that relies on **self-attention** (#self-attention) mechanisms to transform a sequence of input **embeddings** (#embeddings) into a sequence of output embeddings without relying on **convolutions** (#convolution) or **recurrent neural networks** (#recurrent_neural_network). A Transformer can be viewed as a stack of self-attention layers.

abc

Updated Feb 11, 2020

A Transformer can include any of the following:

- an **encoder** (#encoder)
- a **decoder** (#decoder)
- both an encoder and decoder

An **encoder** transforms a sequence of embeddings into a new sequence of the same length. An encoder includes N identical layers, each of which contains two sub-layers. These two sub-layers are applied at each position of the input embedding sequence, transforming each element of the sequence into a new embedding. The first encoder sub-layer aggregates information from across the input sequence. The second encoder sub-layer transforms the aggregated information into an output embedding.

➤ Based on this (#recommendation)

A **decoder** transforms a sequence of input embeddings into a sequence of output embeddings, possibly with a different length. A decoder also includes N identical layers with three sub-layers, two of which are similar to the encoder sub-layers. The third decoder sub-layer takes the output of the encoder and applies the **self-attention** (#self-attention) mechanism to gather information from it.

The blog post **Transformer: A Novel Neural Network Architecture for Language Understanding** (<https://ai.googleblog.com/2017/08/transformer-novel-neural-network.html>) provides a good introduction to Transformers.

unsupervised machine learning

Training a **model** (#model) to find patterns in a dataset, typically an unlabeled dataset.

The most common use of unsupervised machine learning is to cluster data into groups of similar examples. For example, an unsupervised machine learning algorithm can cluster songs together based on various properties of the music. The resulting clusters can become an input to other machine learning algorithms (for example, to a music recommendation service).

➤ **Based on this** (#recommendation)

➤ **Based on this**

Clustering can be helpful in domains where true labels are hard to obtain. For example, in domains such as anti-abuse and fraud, clusters can help humans better understand the data.

Another example of unsupervised machine learning is **principal component analysis (PCA)**.

(https://en.wikipedia.org/wiki/Principal_component_analysis). For example, applying PCA on a dataset containing the contents of millions of shopping carts might reveal that shopping carts containing lemons frequently also contain antacids.

Compare with **supervised machine learning** (#supervised_machine_learning).

user matrix

In **recommendation systems** (#recommendation_system), an **embedding** (#embeddings) generated by **matrix factorization** (#matrix_factorization) that holds latent signals about user preferences. Each row of the user matrix holds information about the relative strength of various latent signals for a single user. For example, consider a movie recommendation system. In this system, the latent signals in the user matrix might represent each user's interest in particular genres, or might be harder-to-interpret signals that involve complex interactions across multiple factors.

The user matrix has a column for each latent feature and a row for each user. That is, the user matrix has the same number of rows as the target matrix that is being factorized. For example, given a movie recommendation system for 1,000,000 users, the user matrix will have 1,000,000 rows.

word embedding

abc

Representing (#representation) each word in a word set within an **embedding** (#embeddings); that is, representing each word as a vector of floating-point values between 0.0 and 1.0. Words with similar meanings have more-similar representations than words with different meanings. For example, *carrots*, *celery*, and *cucumbers* would all have relatively similar representations, which would be very different from the representations of *airplane*, *sunglasses*, and *toothpaste*.

➤ **Based on this** (#recommendation)
